## Climatological seasonal variation of North Sea waterbudget [ $10^{12}\text{kg month}^{-1}$ ]

While Baltic inflow dominates the seasonal cycle of salinity, Atlantic inflow is thought to dominate mean salinity of the North Sea

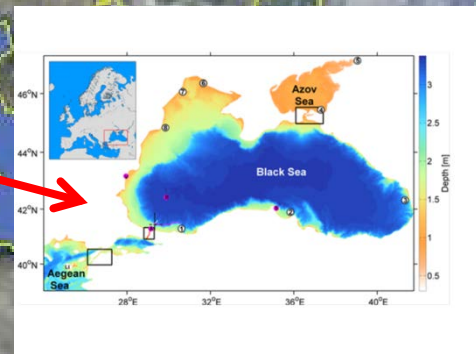

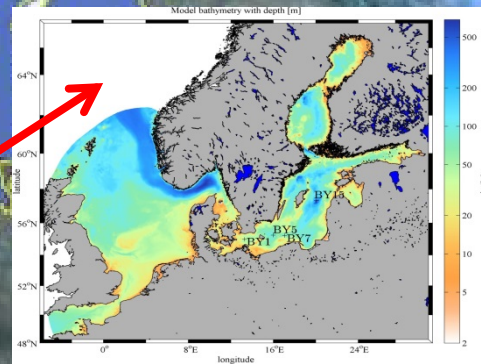

*Stanev et al. (2017): "Obviously, the use of a mixture of the 6-hourly atmospheric reanalysis data, daily data at the open boundaries, and climatological runoff data decreases the realism of simulations. Of particular concern is the missing short-term variability of river runoff, for which no reliable data for all important rivers in the studied region exist"*

Water cycle and the challenge of basin inter-connections

# The model

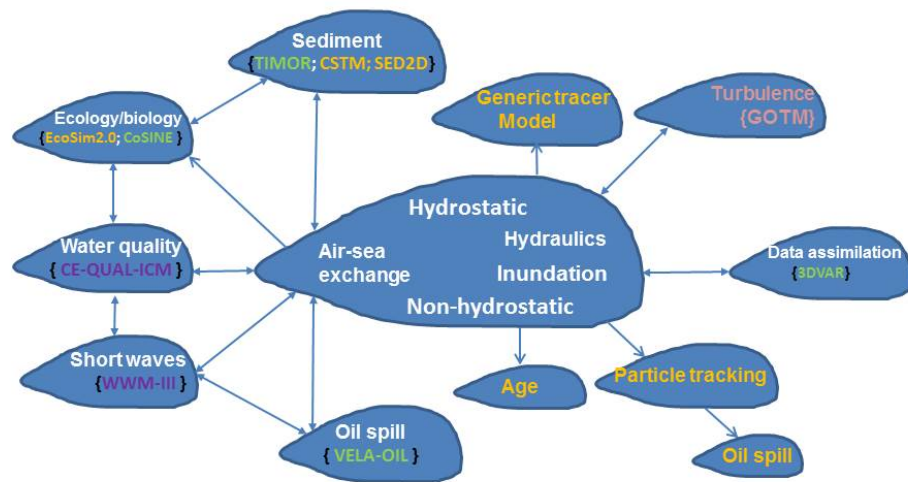

*Semi-implicit Cross-scale Hydrosience Integrated System*  
*Model; [www.schism.wiki](http://www.schism.wiki)*

3D, primitive equations, unstructured-grid.

- Upgrade from an existing model (*SELFE*, : A *Semi-implicit Eulerian-Lagrangian Finite Element* model for cross-scale ocean circulation).
- Uses hybrid finite element and finite volume approach.
- *New viscosity formulation* (effectively filter out spurious modes without introducing excessive dissipation).

## SCHISM modeling system

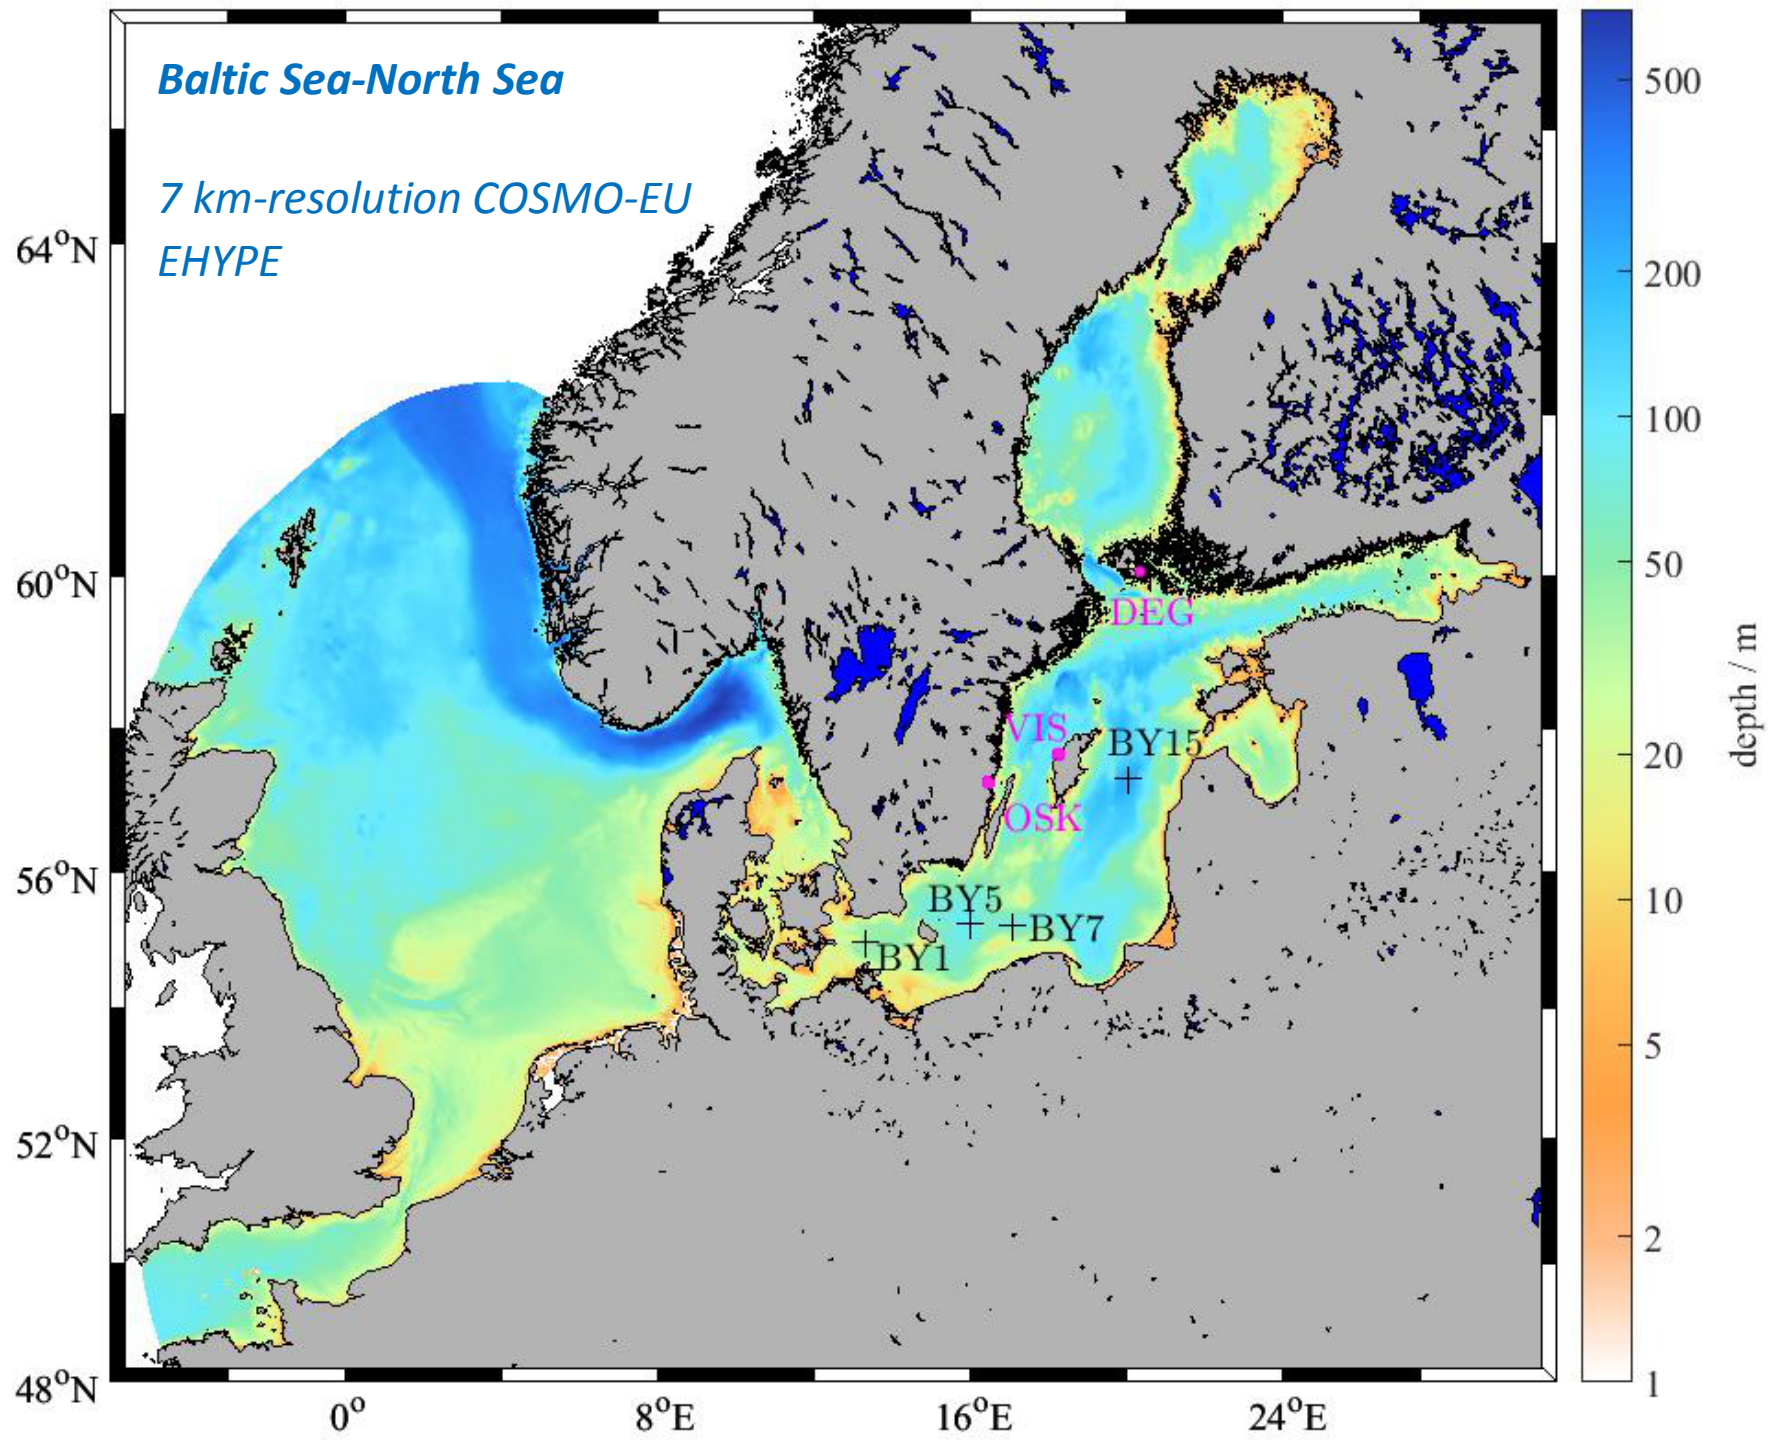

Open-released Ready-to-be-released In-development Free-from-web

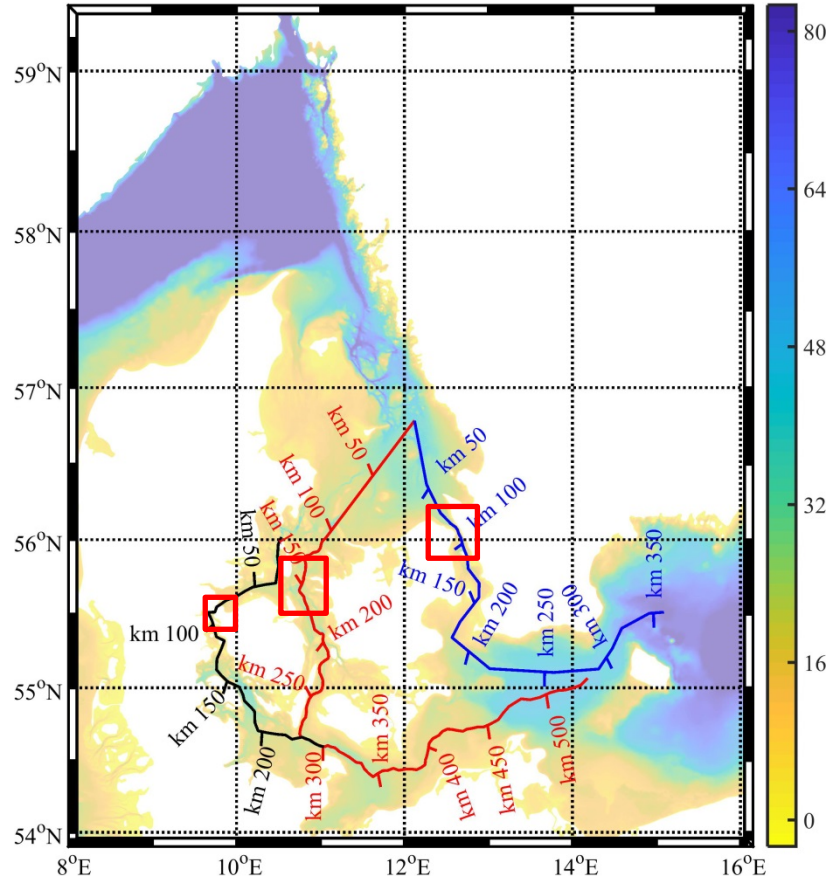

- New higher-order implicit advection scheme for transport (TVD<sup>2</sup>) is proposed to effectively handle a wide range of Courant numbers
- Addition of *quadrangular* elements into the model
- Flexible vertical grid system (Zhang et al. 2015, OM)
- *Model polymorphism* that unifies 1D/2DH/2DV/3D cells in a single model grid.

**Elbe: Salt - Spring Mean**

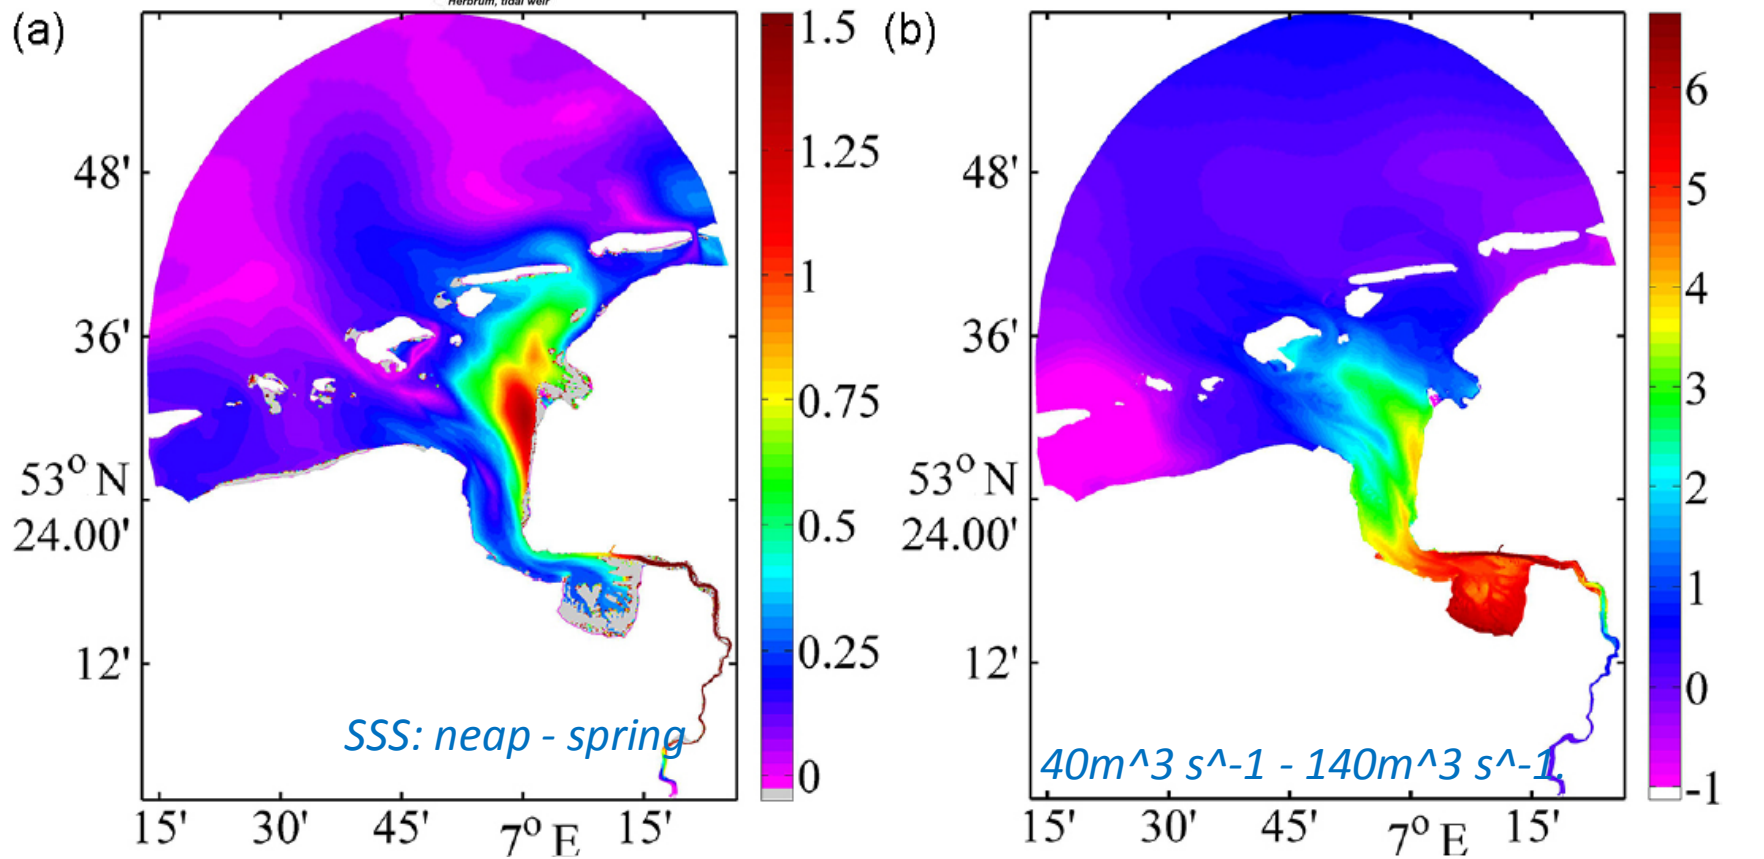

*Model validation: Salinity front as seen by the model and observations*

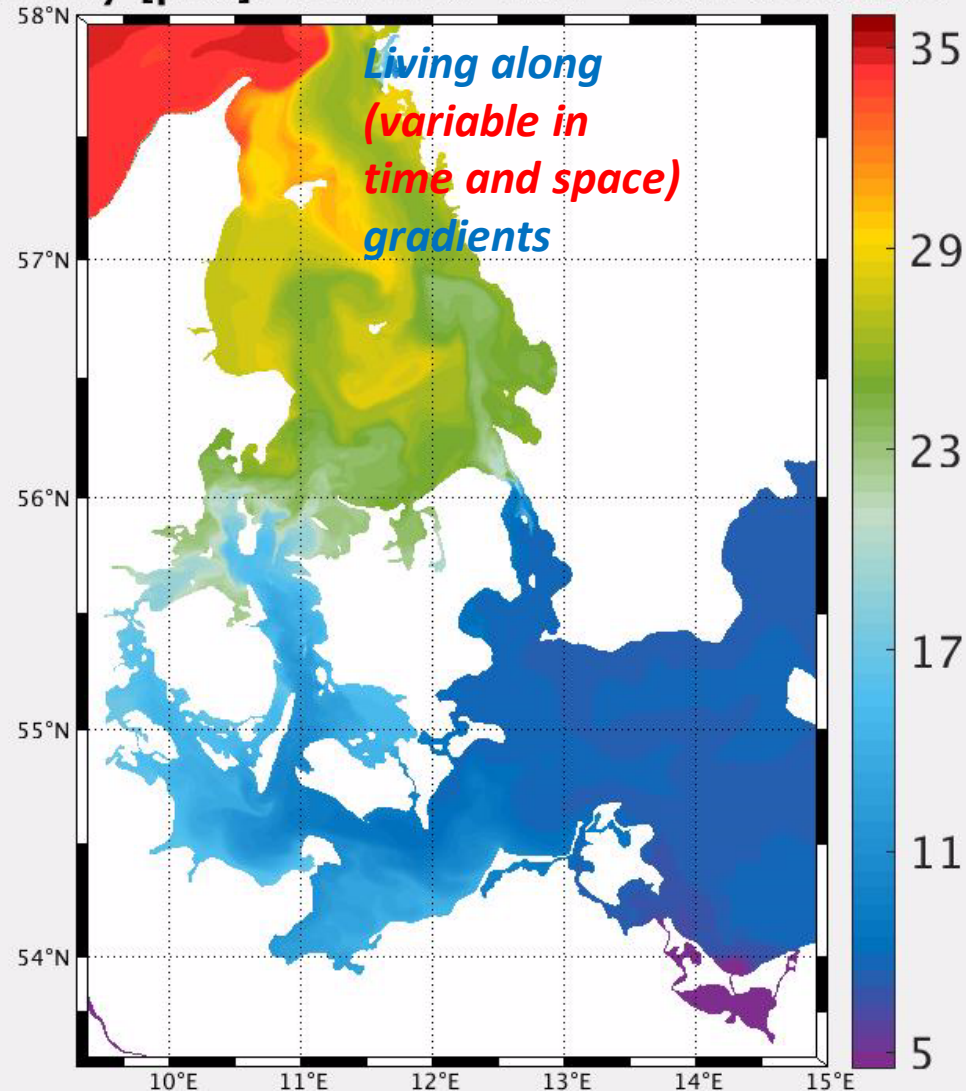

## Conclusions:

1. The benefit of using unstructured-grid models
2. Validation of exchanges in the straits simulated in different models
3. Understanding of physics of estuaries and straits.
4. Adequately account for the coupling between hydrology and oceanography
